#### Анотація

CW-complexes are central to both homotopy theory and homotopy type theory (HoTT) and are encoded in cubical theorem-proving systems as higher inductive types (HIT), similar to recursive trees for (co)inductive types. We explore the basic primitives of homotopy theory, which are considered as a foundational basis in theorem-proving systems.

Keywords: Homotopy Theory, Type Theory

## 1 CW-Complexes

CW-complexes are spaces constructed by attaching cells of various dimensions. In HoTT, they are encoded as higher inductive types (HIT), where cells are constructors for points and paths.

**Definition 1.** (Cell Attachment). The attachment of an *n*-cell to a space X along  $f: S^{n-1} \to X$  is a pushout:

$$S^{n-1} \xrightarrow{f} X$$

$$\downarrow^{\iota} \qquad \qquad \downarrow^{j}$$

$$D^{n} \xrightarrow{g} X \cup_{f} D^{n}$$

Here,  $\iota: S^{n-1} \hookrightarrow D^n$  is the boundary inclusion, and  $X \cup_f D^n$  is the pushout that attaches an n-cell to X via f. The result depends on the homotopy class of f.

**Definition 2.** (CW-Complex). A CW-complex is a space X, constructed inductively by attaching cells, with a skeletal filtration:

- (-1)-skeleton:  $X_{-1} = \emptyset$ .
- For  $n \geq 0$ , the *n*-skeleton  $X_n$  is obtained by attaching *n*-cells to  $X_{n-1}$ . For indices  $J_n$  and maps  $\{f_j: S^{n-1} \to X_{n-1}\}_{j \in J_n}, X_n$  is the pushout:

$$\coprod_{j \in J_n} S^{n-1} \xrightarrow{\coprod f_j} X_{n-1} 
\downarrow \coprod_{\iota_j} \qquad \downarrow_{\iota_n} 
\coprod_{j \in J_n} D^n \xrightarrow{\coprod g_j} X_n$$

where  $\coprod_{j\in J_n} S^{n-1}$ ,  $\coprod_{j\in J_n} D^n$  are disjoint unions, and  $i_n: X_{n-1}\hookrightarrow X_n$  is the inclusion.

• *X* is the colimit:

$$\emptyset = X_{-1} \hookrightarrow X_0 \hookrightarrow X_1 \hookrightarrow \ldots \hookrightarrow X,$$

where  $X_n$  is the *n*-skeleton, and  $X = \operatorname{colim}_{n \to \infty} X_n$ . The sequence is the skeletal filtration.

In HoTT, CW-complexes are higher inductive types (HIT) with constructors for cells and paths for attachment.

#### 1.1 Introduction: Countable Constructors

Some HITs require an infinite number of constructors for spaces, such as Eilenberg-MacLane spaces or the infinite sphere  $S^{\infty}$ .

```
\begin{array}{lll} def \ S^{\infty} \ : \ U \\ := \ inductive \ \left\{ \begin{array}{ll} base \\ & | \ loop \ (n \colon \, \mathbb{N}) \ : \ base \, \equiv \, base \\ & | \end{array} \right. \end{array}
```

Challenges include type checking, computation, and expressiveness.

Agda Cubical uses cubical primitives to handle HITs, supporting infinite constructors via HITs indexed by natural numbers, as colimits.

## 1.2 Motivation: Higher Inductive Types

HITs in HoTT enable direct encoding of topological spaces, such as CW-complexes. In homotopy theory, spaces are constructed by attaching cells via attaching maps. HoTT views types as spaces, elements as points, and equalities as paths, making HITs a natural choice. Standard inductive types cannot capture higher homotopies, but HITs allow constructors for points and paths. For example, the circle  $S^1$  (Definition 2) has a base point and a loop, encoding its fundamental group  $\mathbb Z$ . HITs avoid the use of multiple quotient spaces, preserving the synthetic nature of HoTT. In cubical type theory, paths are intervals (e.g.,  $\langle i \rangle$ ) with computational content, unlike propositional equalities, enabling efficient type checking in tools such as Agda Cubical.

## 1.3 Metatheory: Cohesive Topoi

#### 1.3.1 Geometric Proofs

$$\Re \dashv \Im \dashv \&$$

For differential geometry, type theory incorporates primitive axioms of categorical meta-theoretical models of three Schreiber-Shulman functors: infinitesimal neighborhood ( $\Im$ ), reduced modality ( $\Re$ ), and infinitesimal discrete neighborhood (&).

- 1.3.2 Flat Proofs
- 1.3.3 Sharp Proofs
- 1.3.4 Bose Proofs
- 1.3.5 Fermi Proofs
- 1.3.6 Linear Proofs

For engineering applications (e.g., Milner's  $\pi$ -calculus, quantum computing) and linear type theory, type theory embeds linear proofs based on the adjunction of the tensor and linear function spaces:  $(A \otimes B) \multimap A \simeq A \multimap (B \multimap C)$ , represented in a symmetric monoidal category **D** for a functor [A, B] as:  $\mathbf{D}(A \otimes B, C) \simeq \mathbf{D}(A, [B, C])$ .

# 2 Higher Inductive Types

CW-complexes are central to HoTT and appear in cubical type checkers as HITs. Unlike inductive types (recursive trees), HITs encode CW-complexes, capturing points (0-cells) and higher paths (n-cells). The definition of an HIT specifies a CW-complex through cubical composition, an initial algebra in the cubical model.

## 2.1 Suspension

The suspension  $\Sigma A$  of a type A is a higher inductive type that constructs a new type by adding two points, called poles, and paths connecting each point of A to these poles. It is a fundamental construction in homotopy theory, often used to shift homotopy groups, e.g., obtaining  $S^{n+1}$  from  $S^n$ .

**Definition 3.** (Formation). For any type  $A : \mathcal{U}$ , there exists a suspension type  $\Sigma A : \mathcal{U}$ .

**Definition 4.** (Constructors). For a type  $A: \mathcal{U}$ , the suspension  $\Sigma A: \mathcal{U}$  is generated by the following higher inductive compositional structure:

$$\Sigma := \begin{cases} \text{north} \\ \text{south} \\ \text{merid} : (a:A) \to \text{north} \equiv \text{south} \end{cases}$$

```
\begin{array}{lll} \text{def } \Sigma \ (A \colon U) \ : \ U \\ := \ inductive \ \left\{ \begin{array}{ll} \text{north} \\ \mid \ \text{south} \\ \mid \ \text{merid} \ (a \colon A) \ : \ north \ \equiv \ south \end{array} \right. \end{array}
```

**Theorem 1.** (Elimination). For a family of types  $B: \Sigma A \to \mathcal{U}$ , points n: B(north), s: B(south), and a family of dependent paths

```
m: \Pi(a:A), \text{PathOver}(B, \text{merid}(a), n, s),
```

there exists a dependent map  $\operatorname{Ind}_{\Sigma A}: (x:\Sigma A) \to B(x)$ , such that:

$$\begin{cases} \operatorname{Ind}_{\Sigma A}(\operatorname{north}) = n \\ \operatorname{Ind}_{\Sigma A}(\operatorname{south}) = s \\ \operatorname{Ind}_{\Sigma A}(\operatorname{merid}(a, i)) = m(a, i) \end{cases}$$

def PathOver (B:  $\Sigma$  A  $\rightarrow$  U) (a: A) (n: B north) (s: B south) : U := PathP ( $\lambda$  i , B (merid a @ i)) n s

**Theorem 2.** (Computation).

```
\operatorname{Ind}_{\Sigma} A(\operatorname{north}) = n \operatorname{Ind}_{\Sigma} A(\operatorname{south}) = s \operatorname{Ind}_{\Sigma} A(\operatorname{merid}(a, i)) = m(a, i)
```

**Theorem 3.** (Uniqueness). Any two maps  $h_1, h_2 : (x : \Sigma A) \to B(x)$  are homotopic if they agree on north, south, and merid, i.e., if  $h_1(\text{north}) = h_2(\text{north})$ ,  $h_1(\text{south}) = h_2(\text{south})$ , and  $h_1(\text{merid } a) = h_2(\text{merid } a)$  for all a : A.

#### 2.2 Pushout

The pushout (amalgamation) is a higher inductive type that constructs a type by gluing two types A and B along a common type C via maps  $f:C\to A$  and  $g:C\to B$ . It is a fundamental construction in homotopy theory, used to model cell attachment and cofibrant objects, generalizing the topological notion of a pushout.

**Definition 5.** (Formation). For types  $A, B, C : \mathcal{U}$  and maps  $f : C \to A$ ,  $g : C \to B$ , there exists a pushout  $\sqcup (A, B, C, f, g) : \mathcal{U}$ .

**Definition 6.** (Constructors). The pushout is generated by the following higher inductive compositional structure:

$$\sqcup := \begin{cases} \operatorname{po}_1 : A \to \sqcup (A, B, C, f, g) \\ \operatorname{po}_2 : B \to \sqcup (A, B, C, f, g) \\ \operatorname{po}_3 : (c : C) \to \operatorname{po}_1(f(c)) \equiv \operatorname{po}_2(g(c)) \end{cases}$$

**Theorem 4.** (Elimination). For a type  $D: \mathcal{U}$ , maps  $u: A \to D$ ,  $v: B \to D$ , and a family of paths  $p: (c: C) \to u(f(c)) \equiv v(g(c))$ , there exists a map  $\operatorname{Ind}_{\sqcup} : \sqcup (A, B, C, f, g) \to D$ , such that:

$$\begin{cases} \operatorname{Ind}_{\square}(\operatorname{po}_{1}(a)) = u(a) \\ \operatorname{Ind}_{\square}(\operatorname{po}_{2}(b)) = v(b) \\ \operatorname{Ind}_{\square}(\operatorname{po}_{3}(c,i)) = p(c,i) \end{cases}$$

**Theorem 5.** (Computation). For  $x: \sqcup (A, B, C, f, g)$ ,

$$\begin{cases} \operatorname{Ind}_{\square}(\operatorname{po}_{1}(a)) \equiv u(a) \\ \operatorname{Ind}_{\square}(\operatorname{po}_{2}(b)) \equiv v(b) \\ \operatorname{Ind}_{\square}(\operatorname{po}_{3}(c,i)) \equiv p(c,i) \end{cases}$$

**Theorem 6.** (Uniqueness). Any two maps  $u, v : \sqcup (A, B, C, f, g) \to D$  are homotopic if they agree on  $\operatorname{po}_1$ ,  $\operatorname{po}_2$ , and  $\operatorname{po}_3$ , i.e., if  $u(\operatorname{po}_1(a)) = v(\operatorname{po}_1(a))$  for all a : A,  $u(\operatorname{po}_2(b)) = v(\operatorname{po}_2(b))$  for all b : B, and  $u(\operatorname{po}_3(c)) = v(\operatorname{po}_3(c))$  for all c : C.

**Example 1.** (Cell Attachment) The pushout models the attachment of an n-cell to a space X. Given  $f: S^{n-1} \to X$  and inclusion  $g: S^{n-1} \to D^n$ , the pushout  $\sqcup (X, D^n, S^{n-1}, f, g)$  is the space  $X \cup_f D^n$ , attaching an n-disk to X along f.

$$S^{n-1} \xrightarrow{f} X$$

$$\downarrow^g \qquad \qquad \downarrow$$

$$D^n \xrightarrow{} X \cup_f D^n$$

### 2.3 Spheres

Spheres are higher inductive types with higher-dimensional paths, representing fundamental topological spaces.

**Definition 7.** (Pointed n-Spheres) The *n*-sphere  $S^n$  is defined recursively as a type in the universe  $\mathcal{U}$  using general recursion over dimensions:

$$\mathbb{S}^n := \begin{cases} \text{point} : \mathbb{S}^n, \\ \text{surface} : < i_1, \dots i_n > [\ (i_1 = 0) \to \text{point}, (i_1 = 1) \to \text{point}, \ \dots \\ (i_n = 0) \to \text{point}, (i_n = 1) \to \text{point} \ ] \end{cases}$$

**Definition 8.** (n-Spheres via Suspension) The n-sphere  $S^n$  is defined recursively as a type in the universe  $\mathcal{U}$  using general recursion over natural numbers  $\mathbb{N}$ . For each  $n \in \mathbb{N}$ , the type  $S^n : \mathcal{U}$  is defined as:

$$\mathbb{S}^n := \begin{cases} S^0 = \mathbf{2}, \\ S^{n+1} = \Sigma(S^n). \end{cases}$$

 $\mathsf{def} \;\; \mathsf{sphere} \;\; \colon \; \mathbb{N} \; \to \; \mathsf{U} \; := \; \mathbb{N}\text{-iter} \;\; \mathsf{U} \;\; \mathbf{2} \;\; \Sigma$ 

This iterative definition applies the suspension functor  $\Sigma$  to the base type **2** (0-sphere) n times to obtain  $S^n$ .

**Example 2.** (Sphere as CW-Complex) The n-sphere  $S^n$  can be constructed as a CW-complex with one 0-cell and one n-cell:

$$\begin{cases} X_0 = \{\text{base}\}, \text{ one point} \\ X_k = X_0 \text{ for } 0 < k < n, \text{ no additional cells} \\ X_n : \text{Attachment of an } n\text{-cell to } X_{n-1} = \{\text{base}\} \text{ along } f : S^{n-1} \to \{\text{base}\} \end{cases}$$

The constructor cell attaches the boundary of the n-cell to the base point, yielding the type  $S^n$ .

## 2.4 Hub and Spokes

The hub and spokes construction  $\odot$  defines an n-truncation, ensuring that the type has no non-trivial homotopy groups above dimension n. It models the type as a CW-complex with a hub (central point) and spokes (paths to points).

**Definition 9.** (Formation). For types  $S, A : \mathcal{U}$ , there exists a hub and spokes type  $\odot (S, A) : \mathcal{U}$ .

**Definition 10.** (Constructors). The hub and spokes type is freely generated by the following higher inductive compositional structure:

$$\odot := \begin{cases} \text{base} : A \to \odot (S, A) \\ \text{hub} : (S \to \odot (S, A)) \to \odot (S, A) \\ \text{spoke} : (f : S \to \odot (S, A)) \to (s : S) \to \text{hub}(f) \equiv f(s) \end{cases}$$

**Theorem 7.** (Elimination). For a family of types  $P: \operatorname{HubSpokes} SA \to \mathcal{U}$ , maps phase :  $(x:A) \to P(\operatorname{base} x)$ , phub :  $(f:S \to \operatorname{HubSpokes} SA) \to P(\operatorname{hub} f)$ , and a family of paths pspoke :  $(f:S \to \operatorname{HubSpokes} SA) \to (s:S) \to \operatorname{PathP}(< i > P(\operatorname{spoke} fs@i))$  (phub f) (P(fs)), there exists a map hubSpokesInd :  $(z:\operatorname{HubSpokes} SA) \to P(z)$ , such that:

$$\begin{cases} \operatorname{Ind}_{\odot}\left(\operatorname{base}x\right) = \operatorname{pbase}x\\ \operatorname{Ind}_{\odot}\left(\operatorname{hub}f\right) = \operatorname{phub}f\\ \operatorname{Ind}_{\odot}\left(\operatorname{spoke}fs@i\right) = \operatorname{pspoke}fs@i\end{cases}$$

#### 2.5 Truncation

#### **Set Truncation**

**Definition 11.** (Formation). Set truncation (0-truncation), denoted  $||A||_0$ , ensures that the type is a set, with homotopy groups vanishing above dimension 0.

**Definition 12.** (Constructors). For  $A : \mathcal{U}$ ,  $||A||_0 : \mathcal{U}$  is defined by the following higher inductive compositional structure:

$$\|_{-}\|_{0} := \begin{cases} \text{inc} : A \to \|A\|_{0} \\ \text{squash} : (a, b : \|A\|_{0}) \to (p, q : a \equiv b) \to p \equiv q \end{cases}$$

**Theorem 8.** (Elimination  $||A||_0$ ) For a set  $B: \mathcal{U}$  (i.e., isSet(B)), and a map  $f: A \to B$ , there exists setTruncRec:  $||A||_0 \to B$ , such that  $\operatorname{Ind}_{||A||_0}(\operatorname{inc}(a)) = f(a)$ .

#### **Groupoid Truncation**

**Definition 13.** (Formation). Groupoid truncation (1-truncation), denoted  $||A||_1$ , ensures that the type is a 1-groupoid, with homotopy groups vanishing above dimension 1.

**Definition 14.** (Constructors). For  $A : \mathcal{U}$ ,  $||A||_1 : \mathcal{U}$  is defined by the following higher inductive compositional structure:

$$\|_{-}\|_{1} := \begin{cases} \text{inc} : A \to \|A\|_{1} \\ \text{squash} : (a, b : \|A\|_{1}) \to (p, q : a \equiv b) \to (r, s : p \equiv q) \to r \equiv s \end{cases}$$

**Theorem 9.** (Elimination  $||A||_1$ ) For a 1-groupoid  $B : \mathcal{U}$  (i.e., isGroupoid(B)), and a map  $f : A \to B$ , there exists  $\operatorname{Ind}_{||A||_1} : ||A||_1 \to B$ , such that  $\operatorname{Ind}_{||A||_1}(\operatorname{inc}(a)) = f(a)$ .

### 2.6 Quotients

#### Set Quotient Spaces

Quotient spaces are a powerful computational tool in type theory, embedded in the core of Lean.

**Definition 15.** (Formation). Set quotient spaces construct a type A, quotiented by a relation  $R: A \to A \to \mathcal{U}$ , ensuring that the result is a set.

**Definition 16.** (Constructors). For a type  $A:\mathcal{U}$  and a relation  $R:A\to A\to \mathcal{U}$ , the set quotient space  $A/R:\mathcal{U}$  is freely generated by the following higher inductive compositional structure:

$$A/R := \begin{cases} \operatorname{quot} : A \to A/R \\ \operatorname{ident} : (a, b : A) \to R(a, b) \to \operatorname{quot}(a) \equiv \operatorname{quot}(b) \\ \operatorname{trunc} : (a, b : A/R) \to (p, q : a \equiv b) \to p \equiv q \end{cases}$$

**Theorem 10.** (Elimination). For a family of types  $B: A/R \to \mathcal{U}$  with isSet(Bx), and maps  $f: (x:A) \to B(\operatorname{quot}(x)), \ g: (a,b:A) \to (r:R(a,b)) \to \operatorname{PathP}(< i > B(\operatorname{ident}(a,b,r) @ i))(f(a))(f(b)), \text{ there exists } \operatorname{Ind}_{A/R}: \Pi(x:A/R), B(x), \text{ such that } \operatorname{Ind}_{A/R}(\operatorname{quot}(a)) = f(a).$ 

#### **Groupoid Quotient Spaces**

**Definition 17.** (Formation). Groupoid quotient spaces extend set quotient spaces to produce a 1-groupoid, including constructors for higher paths. Groupoid quotient spaces construct a type A, quotiented by a relation  $R: A \to A \to \mathcal{U}$ , ensuring that the result is a groupoid.

**Definition 18.** (Constructors). For a type  $A:\mathcal{U}$  and a relation  $R:A\to A\to \mathcal{U}$ , the groupoid quotient space  $A//R:\mathcal{U}$  includes constructors for points, paths, and higher paths, ensuring a 1-groupoid structure.

## 2.7 Wedge

The wedge of two pointed types A and B, denoted  $A \vee B$ , is a higher inductive type representing the union of A and B with identified base points. Topologically, it corresponds to  $A \times \{y_0\} \cup \{x_0\} \times B$ , where  $x_0$  and  $y_0$  are the base points of A and B, respectively.

**Definition 19.** (Formation). For pointed types A, B: pointed, the wedge  $A \lor B$ :  $\mathcal{U}$ .

**Definition 20.** (Constructors). The wedge is generated by the following higher inductive compositional structure:

$$\forall := \begin{cases} \text{winl} : A.1 \to A \lor B \\ \text{winr} : B.1 \to A \lor B \\ \text{wglue} : \text{winl}(A.2) \equiv \text{winr}(B.2) \end{cases}$$

```
\begin{array}{lll} def \ \lor \ (A : pointed) \ (B : pointed) \ : \ U \\ := inductive \ \{ \ winl \ (a : A.1) \\ & | \ winr \ (b : B.1) \\ & | \ wglue \ : \ winl(A.2) \ \equiv \ winr(B.2) \\ & \} \end{array}
```

**Theorem 11.** (Elimination). For a type  $P: A \vee B\mathcal{U}$ , maps  $f: A.1 \to C$ ,  $g: B.1 \to C$ , and a path p: PathOverlue(P, f(A.2), g(B.2)), there exists a map  $\mathrm{Ind}_{\vee}: A \vee B \to C$ , such that:

$$\begin{cases} \operatorname{Ind}(\operatorname{winl}(a)) = f(a) \\ \operatorname{Ind}(\operatorname{winr}(b)) = g(b) \\ \operatorname{Ind}(\operatorname{wglue}(x)) = p(x) \end{cases}$$

**Theorem 12.** (Computation). For z: Wedge AB,

$$\begin{cases} \operatorname{Ind}_{\vee}(\operatorname{winl} a) \equiv f(a) \\ \operatorname{Ind}_{\vee}(\operatorname{winr} b) \equiv g(b) \\ \operatorname{Ind}_{\vee}(\operatorname{wglue} @ x) \equiv p @ x \end{cases}$$

**Theorem 13.** (Uniqueness). Any two maps  $h_1, h_2$ : Wedge  $AB \to C$  are homotopic if they agree on winl, winr, and wglue, i.e., if  $h_1(\text{winl } a) = h_2(\text{winl } a)$  for all  $a: A.1, h_1(\text{winr } b) = h_2(\text{winr } b)$  for all b: B.1, and  $h_1(\text{wglue}) = h_2(\text{wglue})$ .

#### 2.8 Smash Product

The smash product of two pointed types A and B, denoted  $A \wedge B$ , is a higher inductive type that quotients the product  $A \times B$  by the pushout  $A \sqcup B$ . It represents the space  $A \times B/(A \times \{y_0\} \cup \{x_0\} \times B)$ , collapsing the wedge to a single point.

**Definition 21.** (Formation). For pointed types A, B: pointed, the smash product  $A \wedge B : \mathcal{U}$ .

**Definition 22.** (Constructors). The smash product is generated by the following higher inductive compositional structure:

```
A \wedge B := \begin{cases} \text{basel} : A \wedge B \\ \text{baser} : A \wedge B \end{cases}\text{proj}(x : A.1)(y : B.1) : A \wedge B \\ \text{gluel}(a : A.2) : \text{proj}(a, B.2) \equiv \text{basel} \\ \text{gluer}(b : B.2) : \text{proj}(A.2, b) \equiv \text{baser} \end{cases}
```

**Theorem 14.** (Elimination). For a family of types  $P: \text{Smash } AB \to \mathcal{U}$ , points pbasel: P(basel), pbaser: P(baser), maps pproj:  $(x:A.1) \to (y:B.1) \to P(\text{proj } xy)$ , and a family of paths pgluel:  $(a:A.1) \to \text{pproj}(a,B.2) \equiv \text{pbasel}$ , pgluer:  $(b:B.1) \to \text{pproj}(A.2,b) \equiv \text{pbaser}$ , there exists a map  $\text{Ind}_{\wedge}: (z:A \land B) \to P(z)$ , such that:

```
\begin{cases} \operatorname{Ind}_{\wedge} (\operatorname{basel}) = \operatorname{pbasel} \\ \operatorname{Ind}_{\wedge} (\operatorname{baser}) = \operatorname{pbaser} \\ \operatorname{Ind}_{\wedge} (\operatorname{proj} x \, y) = \operatorname{pproj} x \, y \\ \operatorname{Ind}_{\wedge} (\operatorname{gluel} a @ i) = \operatorname{pgluel} a @ i \\ \operatorname{Ind}_{\wedge} (\operatorname{gluer} b @ i) = \operatorname{pgluer} b @ i \end{cases}
```

**Theorem 15.** (Computation). For a family of types  $P: A \wedge B \to \mathcal{U}$ , points pbasel: P(basel), pbaser: P(baser), map pproj:  $(x:A.1) \to (y:B.1) \to P(\text{proj}\,x\,y)$ , and families of paths pgluel:  $(a:A.1) \to \text{PathP}\,(< i > P(\text{gluel}\,a\,@\,i))$  (pproj $\,a\,B.2$ ) pbasel, pgluer:  $(b:B.1) \to \text{PathP}\,(< i > P(\text{gluer}\,b\,@\,i))$  (pproj $\,A.2\,b$ ) pbaser, the map  $\text{Ind}_{\wedge}: (z:A \wedge B) \to P(z)$  satisfies all equations for all variants of the predicate P:

 $\begin{cases} \operatorname{Ind}_{\wedge} \left( \operatorname{basel} \right) \equiv \operatorname{pbasel} \\ \operatorname{Ind}_{\wedge} \left( \operatorname{baser} \right) \equiv \operatorname{pbaser} \\ \operatorname{Ind}_{\wedge} \left( \operatorname{proj} x \, y \right) \equiv \operatorname{pproj} x \, y \\ \operatorname{Ind}_{\wedge} \left( \operatorname{gluel} a @ i \right) \equiv \operatorname{pgluel} a @ i \\ \operatorname{Ind}_{\wedge} \left( \operatorname{gluer} b @ i \right) \equiv \operatorname{pgluer} b @ i \end{cases}$ 

**Theorem 16.** (Uniqueness). For a family of types  $P: A \wedge B \to \mathcal{U}$ , and maps  $h_1, h_2: (z: A \wedge B) \to P(z)$ , if there exist paths  $e_{\text{basel}}: h_1(\text{basel}) \equiv h_2(\text{basel}), e_{\text{baser}}: h_1(\text{baser}) \equiv h_2(\text{baser}), e_{\text{proj}}: (x: A.1) \to (y: B.1) \to h_1(\text{proj} x y) \equiv h_2(\text{proj} x y), e_{\text{gluel}}: (a: A.1) \to \text{PathP}(\langle i > h_1(\text{gluel } a @ i)) \equiv h_2(\text{gluel } a @ i)) (e_{\text{proj}} a B.2) e_{\text{basel}}, e_{\text{gluer}}: (b: B.1) \to \text{PathP}(\langle i > h_1(\text{gluer } b @ i)) \equiv h_2(\text{gluer } b @ i)) (e_{\text{proj}} A.2 b) e_{\text{baser}}, \text{ then } h_1 \equiv h_2, \text{ i.e., there exists a path } (z: A \wedge B) \to h_1(z) \equiv h_2(z).$ 

#### 2.9 Join

The join of two types A and B, denoted  $A \vee B$ , is a higher inductive type that constructs a type by joining each point of A to each point of B via a path. Topologically, it corresponds to the join of spaces, forming a space that interpolates between A and B.

**Definition 23.** (Formation). For types  $A, B : \mathcal{U}$ , the join  $A * B : \mathcal{U}$ .

**Definition 24.** (Constructors). The join is generated by the following higher inductive compositional structure:

$$A \vee B := \begin{cases} \text{joinl} : A \to A \vee B \\ \text{joinr} : B \to A \vee B \\ \text{join}(a : A)(b : B) : \text{joinl}(a) \equiv \text{joinr}(b) \end{cases}$$

**Theorem 17.** (Elimination). For a type  $C: \mathcal{U}$ , maps  $f: A \to C$ ,  $g: B \to C$ , and a family of paths  $h: (a:A) \to (b:B) \to f(a) \equiv g(b)$ , there exists a map  $\operatorname{Ind}_{\vee}: A \vee B \to C$ , such that:

$$\begin{cases} \operatorname{Ind}_{\vee}(\operatorname{joinl}(a)) = f(a) \\ \operatorname{Ind}_{\vee}(\operatorname{joinr}(b)) = g(b) \\ \operatorname{Ind}_{\vee}(\operatorname{join}(a, b, i)) = h(a, b, i) \end{cases}$$

```
\begin{array}{l} \text{def Ind}_{\vee} \ (A \ B \ C \ : \ U) \ (f \ : A \ {\rightarrow} \ C) \ (g \ : B \ {\rightarrow} \ C) \\ \ (h \ : (a \ : A) \ {\rightarrow} \ (b \ : B) \ {\rightarrow} \ Path \ C \ (f \ a) \ (g \ b)) \\ \ : A \lor B \ {\rightarrow} \ C \\ \ := \ split \ \left\{ \begin{array}{l} \text{joinl} \ a \ {\rightarrow} \ f \ a \\ \ | \ \text{joinr} \ b \ {\rightarrow} \ g \ b \\ \ | \ \text{joinn} \ a \ b \ @ \ i \ {\rightarrow} \ h \ a \ b \ @ \ i \\ \end{array} \right.
```

**Theorem 18.** (Computation). For all  $z : A \vee B$ , and predicate P, the rules of Ind $\vee$  hold for all parameters of the predicate P.

**Theorem 19.** (Uniqueness). Any two maps  $h_1, h_2 : A \vee B \to C$  are homotopic if they agree on joinl, joinr, and join.

#### 2.10 Colimit

Colimits construct the limit of a sequence of types, connected by maps, e.g., propositional truncations.

**Definition 25.** (Colimit) For a sequence of types A: nat  $\to \mathcal{U}$  and maps  $f:(n:\mathbb{N})\to An\to A(\operatorname{succ}(n))$ , the colimit type  $\operatorname{colimit}(A,f):\mathcal{U}$ .

$$\operatorname{colim} := \begin{cases} \operatorname{ix} : (n : \operatorname{nat}) \to An \to \operatorname{colimit}(A, f) \\ \operatorname{gx} : (n : \operatorname{nat}) \to (a : A(n)) \to \operatorname{ix}(\operatorname{succ}(n), f(n, a)) \equiv \operatorname{ix}(n, a) \end{cases}$$

**Theorem 20.** (Elimination colimit) For a type P: colimit  $Af \to \mathcal{U}$ , with  $p:(n:\mathrm{nat}) \to (x:An) \to P(\mathrm{ix}(n,x))$  and  $q:(n:\mathrm{nat}) \to (a:An) \to P\mathrm{athP}(\langle i \rangle P(\mathrm{gx}(n,a)@i))(p(\mathrm{succ}\ n)(fna))(pna)$ , there exists  $i:\Pi_{x:\mathrm{colimit}\ Af}P(x)$ , such that  $i(\mathrm{ix}(n,x)) = pnx$ .

## 2.11 Coequalizers

#### Coequalizer

The coequalizer of two maps  $f, g: A \to B$  is a higher inductive type (HIT) that constructs a type consisting of elements in B, where f and g agree, along with paths ensuring this equality. It is a fundamental construction in homotopy theory, capturing the subspace of B where f(a) = g(a) for a: A.

**Definition 26.** (Formation). For types  $A, B : \mathcal{U}$  and maps  $f, g : A \to B$ , the coequalizer coeq  $ABfg : \mathcal{U}$ .

**Definition 27.** (Constructors). The coequalizer is generated by the following higher inductive compositional structure:

$$Coeq := \begin{cases} inC : B \to Coeq(A, B, f, g) \\ glueC : (a : A) \to inC(f(a)) \equiv inC(g(a)) \end{cases}$$

**Theorem 21.** (Elimination). For a type  $C: \mathcal{U}$ , map  $h: B \to C$ , and a family of paths  $y: (x: A) \to \operatorname{Path}_C(h(fx), h(gx))$ , there exists a map coequRec: coeq  $ABfg \to C$ , such that:

$$\begin{cases} \operatorname{coequRec}(\operatorname{inC}(x)) = h(x) \\ \operatorname{coequRec}(\operatorname{glueC}(x,i)) = y(x,i) \end{cases}$$

```
\begin{array}{l} \text{def coequRec } (A \ B \ C : \ U) \ (f \ g : A \longrightarrow B) \ (h: B \longrightarrow C) \\ (y: (x : A) \longrightarrow \text{Path } C \ (h \ (f \ x)) \ (h \ (g \ x))) \\ : (z : \text{coeq } A \ B \ f \ g) \longrightarrow C \\ := \text{split} \ \{ \ \text{inC} \ x \longrightarrow h \ x \ | \ \text{glueC} \ x \ @ \ i \ \longrightarrow y \ x \ @ \ i \ \} \end{array}
```

**Theorem 22.** (Computation). For z: coeq ABfg,

$$\begin{cases} \text{coequRec(inC } x) \equiv h(x) \\ \text{coequRec(glueC } x @ i) \equiv y(x) @ i \end{cases}$$

**Theorem 23.** (Uniqueness). Any two maps  $h_1, h_2 : \text{coeq } ABfg \to C$  are homotopic if they agree on inC and glueC, i.e., if  $h_1(\text{inC } x) = h_2(\text{inC } x)$  for all x : B and  $h_1(\text{glueC } a) = h_2(\text{glueC } a)$  for all a : A.

**Example 3.** (Coequalizer as Subspace) The coequalizer coeq ABfg represents the subspace of B, where f(a) = g(a). For example, if  $A = B = \mathbb{R}$  and  $f(x) = x^2$ , g(x) = x, the coequalizer captures the points where  $x^2 = x$ , i.e.,  $\{0, 1\}$ .

#### Path Coequalizer

The path coequalizer is a higher inductive type that generalizes the coequalizer to handle pairs of paths in B. Given a map  $p:A \to (b_1,b_2:B) \times (\operatorname{Path}_B(b_1,b_2)) \times (\operatorname{Path}_B(b_1,b_2))$ , it constructs a type where elements of A generate pairs of paths between points in B, with paths connecting the endpoints of these paths.

**Definition 28.** (Formation). For types  $A, B : \mathcal{U}$  and a map  $p : A \to (b_1, b_2 : B) \times (b_1 \equiv b_2) \times (b_1 \equiv b_2)$ , there exists a path coequalizer  $\text{Coeq}_{\equiv}(A, B, p) : \mathcal{U}$ .

**Definition 29.** (Constructors). The path coequalizer is generated by the following higher inductive compositional structure:

$$\operatorname{Coequ}_{\equiv} := \begin{cases} \operatorname{inP} : B \to \operatorname{Coeq}_{\equiv}(A, B, p) \\ \operatorname{glueP} : (a : A) \to \operatorname{inP}(p(a).2.2.1@0) \equiv \operatorname{inP}(p(a).2.2.2@1) \end{cases}$$

**Theorem 24.** (Elimination). For a type  $C: \mathcal{U}$ , map  $h: B \to C$ , and a family of paths  $y: (a:A) \to h(p(a).2.2.1@0) \equiv h(p(a).2.2.2@1)$ , there exists a map Ind-Coequ<sub>\equiv</sub>: Coeq<sub>\equiv</sub> $(A, B, p) \to C$ , such that:

$$\begin{cases} \text{coequPRec}(\text{inP}(b)) = h(b) \\ \text{coequPRec}(\text{glueP}(a,i)) = y(a,i) \end{cases}$$

```
\begin{array}{l} \text{def Ind-Coequ}_{\equiv} \ (A \ B \ C \ : \ U) \\ (p : A \to \Sigma \ (b1 \ b2 : B) \ (x: \ Path \ B \ b1 \ b2), \ Path \ B \ b1 \ b2) \\ (h: B \to C) \ (y: \ (a : A) \to Path \ C \ (h \ (((p \ a).2.2.1) \ @ \ 0)) \ (h \ (((p \ a).2.2.2) \ @ \ 1))) \\ : \ (z : coeqP \ A \ B \ p) \to C \\ := \ split \ \{ \ inP \ b \to h \ b \ | \ glueP \ a \ @ \ i \ -> \ y \ a \ @ \ i \ \} \end{array}
```

**Theorem 25.** (Computation). For z : coeqP ABp,

$$\begin{cases} \text{coequPRec}(\text{inP }b) \equiv h(b) \\ \text{coequPRec}(\text{glueP }a @ i) \equiv y(a) @ i \end{cases}$$

**Theorem 26.** (Uniqueness). Any two maps  $h_1, h_2 : \text{coeqP } ABp \to C$  are homotopic if they agree on inP and glueP, i.e., if  $h_1(\text{inP } b) = h_2(\text{inP } b)$  for all b : B and  $h_1(\text{glueP } a) = h_2(\text{glueP } a)$  for all a : A.

## 2.12 K(G,n)

Eilenberg-MacLane spaces K(G,n) have a single non-trivial homotopy group  $\pi_n(K(G,n)) = G$ . They are defined using truncations and suspensions.

**Definition 30.** (K(G,n)) For an abelian group G: abgroup, the type KGn(G): nat  $\to \mathcal{U}$ .

$$K(G,n) := \begin{cases} n = 0 \leadsto \text{discreteTopology}(G) \\ n \ge 1 \leadsto \|\Sigma^{n-1}(K1'(G.1, G.2.1))\|_n \end{cases}$$

$$\begin{array}{lll} def \ KGn \ (G: \ abgroup) \ : \ \mathbf{N} \ {\rightarrow} \ U \\ := \ split \ \{ \ zero \ {\rightarrow} \ discreteTopology \ G \\ & | \ succ \ n \ {\rightarrow} \ nTrunc \ (\Sigma \ (K1' \ (G.1\,,G.2.1)) \ n) \ (succ \ n) \\ & \} \end{array}$$

**Theorem 27.** (Elimination KGn) For  $n \geq 1$ , a type  $B : \mathcal{U}$  with isNGroupoid(B, succ n), and a map f : suspension(K1'G)  $\to B$ , there exists  $\operatorname{rec}_{KGn} : KGnG(\operatorname{succ} n) \to B$ , defined via nTruncRec.

#### 2.13 Localization

Localization constructs an F-local type from a type X, with respect to a family of maps  $F_A: S(a) \to T(a)$ .

**Definition 31.** (Localization Modality) For a family of maps  $F_A: S(a) \to T(a)$ , the F-localization  $L_F^{AST}(X): \mathcal{U}$ .

```
 \begin{aligned} & \text{center}: X \to L_{F_A}(X) \\ & \text{ext}(a:A) \to (S(a) \to L_{F_A}(X)) : T(a) \to L_{F_A}(X) \\ & \text{isExt}(a:A)(f:S(a) \to L_{F_A}(X)) \to (s:S(a)) : \text{ext}(a,f,F(a,s)) \equiv f(s) \\ & \text{extEq}(a:A)(g,h:T(a) \to L_{F_A}(X)) \\ & (p:(s:S(a)) \to g(F(a,s)) \equiv h(F(a,s))) \\ & (t:T(a)) : g(t) \equiv h(t) \\ & \text{isExtEq}:(a:A)(g,h:T(a) \to L_{F_A}(X)) \\ & (p:(s:S(a)) \to g(F(a,s)) \equiv h(F(a,s))) \\ & (s:S(a)) : \text{extEq}(a,g,h,p,F(a,s) \equiv p(s) \end{aligned}   \begin{aligned} & \text{data Localize (A X: U) (S T: A \to U) (F:(x:A) \to S x \to T x)} \\ & = \text{center (x: X)} \\ & | \text{ ext (a: A) (f: S a \to Localize A X S T F) (t: T a)} \\ & | \text{ isExt (a: A) (f: S a \to Localize A X S T F) (s: S a) < i>} \\ & | (i=0) \to \text{ext a f (F a s) , (i=1) \to f s} \\ & | \text{ extEq (a: A) (g h: T a \to Localize A X S T F) (g (F a s)) (h (F a s)))} \\ & (t: T a) < i > [(i=0) \to g t, (i=1) \to h t] \\ & | \text{ isExtEq (a: A) (g h: T a \to Localize A X S T F)} \\ & (p:(s:S a) \to \text{ Path (T a \to Localize A X S T F) (g (F a s)) (h (F a s)))} \\ & (s:S a) < i > [(i=0) \to \text{ extEq a g h p (F a s) , (i=1) \to p s ]} \end{aligned}
```

**Theorem 28.** (Localization Induction) For any  $P: \Pi_{X:U}L_{F_A}(X) \to U$  with  $\{n, r, s\}$ , satisfying coherence conditions, there exists  $i: \Pi_{x:L_{F_A}(X)}P(x)$ , such that  $i \cdot \operatorname{center}_X = n$ .

## Conclusion

HITs directly encode CW-complexes in HoTT, bridging topology and type theory. They enable the analysis and manipulation of homotopical types.
